

JWPlayer Embedded Video Macros

If you have an .mp4 or .flv file that uses the H.264 video codec, you can attach the video to any page in the DuraSpace wiki and allow it to be played embedded inside that page, with the help of [jwplayer](#). I've created two custom Confluence macros for this purpose, **mp4** and **flv**.

Example

This wiki markup embeds an mp4 video:

```
{mp4:num=1|width=352|height=240|url=https://wiki.duraspace.org/download/attachments/22546192/example-video.mp4}
```

The **width**, **height**, and **url** parameters are self-explanatory, but what is the **num** parameter? It's just a number...any number. It's a little strange, but in order for the macro to work, each embedded video on a single confluence page must have a unique value specified for num.

Here's what it looks like when viewed on a page:

Flash required for inline viewing.

*Note: If you have an flv video, just use **flv** as the name of the macro instead of **mp4**.*
