# Glossary

Fedora 4 is a Linked Data Platform server as defined by the Linked Data Platform 1.0 specification. As such, many of the terms in this glossary are drawn directly from this specification.

- Access Role
- Binary
- Checksum
- Children
- Compact Node Definition (CND)
   Container (formerly known as: Object
- Container (formerly known as: Object)
- DatastreamDissemination
- Federation (aka Projection)
- Fixity
- Indexer
- jcr/xml
- Linked Data Platform (LDP)
- Managed External Content
- Namespace
- NonRdfSourceDescription (formerly known as: datastream)
- Object
- Policy Enforcement Point (aka PEP)
- Predicate Prefix
- Projection (aka: Federation)
- Properties
- rdf:type
- Repository
- Resource
- Tombstone
- Transactions
- Triple
- Uniform resource identifier (URI)
- Universally Unique Identifier (UÚID)
- Version

## Access Role

A named role, such as "writer", that is assigned to a user, group or some other identifying principal within part of the repository. Roles may be used by the policy enforcement point (PEP) to authorize actions taken in the repository.

# Binary

A binary in a Fedora repository is a nonRdfSource resource. In other contexts, binaries would sometimes be described as bit-streams or files. Binaries are always accompanied by a nonRdfSourceDescription.

#### Checksum

A computed fingerprint for binary content, used to ensure a complete transfer or the fixity of stored information. Fedora supports the SHA-1 checksum algorithm for safely uploading content.

# Children

The resources which are immediate children of a given container. Properties are not counted as children.

# **Compact Node Definition (CND)**

A file format defined by JCR here that allows for the definition of new *resource* types and *namespaces*. It is highly recommended that users do not modify Fedora 4's CND file, as such modifications may limit the ability for subsequent Fedora version upgrades of the repository installation.

# Container (formerly known as: Object)

A container is a *resource* that represents intellectual entities and can also be used to aggregate other *resources* in a Fedora repository. Containers may container other containers or *binaries* and their *nonRdfSourceDescriptions*.

#### Datastream

See: NonRdfSourceDescription

#### Dissemination

An approach previously available in Fedora 3 that allowed for binding a service to a content model. Note: disseminators, as such, do not exist in Fedora 4.

# Federation (aka Projection)

#### See: Projection

## Fixity

Fixity is the integrity of stored information over time. Fedora performs fixity checks on demand by comparing a stored checksum with one that is newly computed.

## Indexer

Creating, modifying or deleting resources in the repository generates events. The indexer monitors and processes these events; by ingesting relevant RDF to an external triplestore, for example.

## jcr/xml

An XML document, the schema of which is defined by the JCR specification, which has a format that represents JCR resources. It can be used to export /import a set of *resources* and *properties* into a repository.

# Linked Data Platform (LDP)

The W3C Linked Data Platform (LDP) specification describes a set of best practices and simple approach for a read-write Linked Data architecture, based on HTTP access to web resources that describe their state using the RDF data model. Fedora 4 implements the LDP specification for create, read, update and delete (CRUD), allowing HTTP, REST, and linked data clients to make requests to Fedora 4.

## **Managed External Content**

Refers to content that sits outside the Fedora-configured datastore, but is managed by Fedora through a *projection*. Managed external content can be accessible via the Fedora API as well as have Fedora-managed audits.

#### Namespace

A namespace is a container for a set of identifiers (also known as symbols, names). In Fedora 4, *resource* properties may belong to any namespace providing semantic assertions that support interoperable metadata. Namespaces are restricted to being an empty string or to a URI as defined in section 3 of RFC3986. An example of a namespace would be "http://purl.org/dc/elements/1.1/".

## NonRdfSourceDescription (formerly known as: datastream)

A nonRdfSourceDescription is a *resource* that describes a binary *resource* within the Fedora repository. A nonRdfSourceDescription is always accompanied by a *binary*, and vice versa.

#### Object

See: Container

# Policy Enforcement Point (aka PEP)

This is a pluggable component in the Fedora framework that is responsible for authorizing all actions take on resources.

#### Predicate

A predicate expresses a relationship between the subject and the object of a triple.

# Prefix

Typically a short string representation of an associated *namespace*. For example the prefix "dc" could be used to represent the namespace "http://purl.org /dc/elements/1.1/". If we wanted to access an element (e.g. "contributor") within that namespace we could do it with the prefix "dc:contributor" or in the full form "http://purl.org/dc/elements/1.1/contributor".

#### Prefixes are limited to the following grammar:

```
LocalName ::= ValidString - SelfOrParent

/* Any ValidString except SelfOrParent */

SelfOrParent ::= '.' | '..'

ValidString ::= ValidChar {ValidChar}

ValidChar ::= XmlChar - InvalidChar

/* Any XmlChar except InvalidChar */

InvalidChar ::= '/' | ':' | '[' | ']' | '|' | '*'

XmlChar ::= /* Any character that matches the Char production at http://www.w3.org/TR/xml/#NT-Char */
```

# **Projection (aka: Federation)**

The process by which a repository may present resources through the API that are actually stored in a different system, such as a file system or database.

# Properties

Properties are name/value pairs that belong to *resources*. The name of a property can be any term from a *namespaced* vocabulary. When RDF is generated in response to a request for a *resource* that contains properties, the RDF will contain *triples* for each property where the subject of the *triple* is the resource itself, the *predicate* of the *triple* is the property name, and the object of the triple is the value of the property. Property values can be of any valid *rdf:type*.

## rdf:type

Containers are defined by one or more rdf:types that describe the nature of the container. Similarly, every property will be an instance of a single rdf: type. The official definition can be found here.

## Repository

A repository is a single, self-contained persistent store of information plus the software that is used to access and update that information. Fedora is a repository.

## Resource

Resources are the primary organizational structure in the repository. A resource is any web-addressable entity, such as a *container*, a *nonRdfSourceDescription*, or a *binary*. Every resource has a name and a unique identifier, and can also be identified by a path. They are comprised of zero or more properties / child resources.

#### Tombstone

A tombstone is a repository resource indicating that a container, binary, or nonRdfSourceDescription used to exist at a given URL. A tombstone is created when a resource is deleted or moved.

## Transactions

A transaction represents a series of changes to the repository that must execute successfully and completely or not at all. Transactions should be used to ensure consistency. Each transaction succeeds or fails as a complete unit; it cannot remain in an intermediate state.

## Triple

A triple is a fundamental building block of RDF. It consists of: a subject, *predicate*, and an object. In this way, a triple can describe a relationship (via the *pre dicate*) of the subject to the object. The official definition can be found here.

#### Uniform resource identifier (URI)

A string of characters used to uniquely identify a resource. It is defined in RFC3986, section 3. An example of a URI would be "http://purl.org/dc/elements/1. 1/".

#### **Universally Unique Identifier (UUID)**

A "practically" unique identifier that is used to identify a resource.

#### Version

A snapshot of a resource that is saved in version history for later access.
